 Koji TASAKA (Aichi Prefectural University)*³

$$(k_1 \geq 2, k_2, \dots, k_r \geq 1)$$

For an index $\mathbf{k} = (k_1, \dots, k_r) \in (\mathbb{Z}_{\geq 1})^r$ with $k_1 \geq 2$ the multiple zeta value and the multiple zeta star value are defined by

$$\zeta(k_1, \dots, k_r) = \sum_{m_1 > \dots > m_r > 0} \frac{1}{m_1^{k_1} \dots m_r^{k_r}}, \quad \zeta^*(\mathbf{k}) = \sum_{m_1 \geq \dots \geq m_r > 0} \frac{1}{m_1^{k_1} \dots m_r^{k_r}}.$$

We denote by \mathcal{Z} the \mathbb{Q} -vector space spanned by all multiple zeta values. The space \mathcal{Z} forms a subalgebra of \mathbb{R} over \mathbb{Q} and is the same space with that spanned by multiple zeta star values. In their recent work [3], Kaneko and Zagier introduce two variants of these values, called finite and symmetric multiple zeta values, and give a mysterious conjecture relating them.

Finite multiple zeta values are defined for an index $\mathbf{k} = (k_1, \dots, k_r) \in \mathbb{Z}_{\geq 1}^r$ by

$$\zeta_{\mathcal{A}}(\mathbf{k}) = \left(\sum_{p > m_1 > \dots > m_r > 0} \frac{1}{m_1^{k_1} \dots m_r^{k_r}} \pmod p \right)_p \in \mathcal{A},$$

where \mathcal{A} is the \mathbb{Q} -algebra $\mathcal{A} = (\prod_p \mathbb{F}_p) / (\bigoplus_p \mathbb{F}_p)$ with p running over all primes.

Symmetric multiple zeta values are defined for an index $\mathbf{k} = (k_1, \dots, k_r) \in \mathbb{Z}_{\geq 1}^r$ by

$$\zeta_S(\mathbf{k}) = \sum_{a=0}^r (-1)^{k_1 + \dots + k_a} \zeta^*(k_a, k_{a-1}, \dots, k_1) \zeta^*(k_{a+1}, k_{a+2}, \dots, k_r) \in \mathcal{Z} / \zeta(2) \mathcal{Z},$$

where ζ^* denotes the regularized multiple zeta values defined in [2]. Both, finite and symmetric multiple zeta values, also have star-versions $\zeta_{\mathcal{A}}^*(\mathbf{k}) \in \mathcal{A}$ and $\zeta_S^*(\mathbf{k}) \in \mathcal{Z} / \zeta(2) \mathcal{Z}$, which relate to their non-star version like ζ^* does to ζ . A priori finite and symmetric multiple zeta values are completely different objects, but Kaneko and Zagier gave the following surprising conjecture.

Conjecture 1 (Kaneko–Zagier [3]) *Let $\mathcal{Z}_{\mathcal{A}}$ be the \mathbb{Q} -vector space of finite multiple zeta values. There exists a \mathbb{Q} -algebra isomorphism*

$$\begin{aligned} \varphi_{KZ} : \mathcal{Z}_{\mathcal{A}} &\longrightarrow \mathcal{Z} / \zeta(2) \mathcal{Z}, \\ \zeta_{\mathcal{A}}(\mathbf{k}) &\longmapsto \zeta_S(\mathbf{k}) \pmod{\zeta(2) \mathcal{Z}}. \end{aligned}$$

In our work [1], we study this mysterious relationship between finite and symmetric multiple zeta values by considering the *finite multiple harmonic q -series*, defined for $n \in \mathbb{Z}_{\geq 1}$ and an index $\mathbf{k} = (k_1, \dots, k_r)$ by

$$z_n(\mathbf{k}; q) = \sum_{n > m_1 > \dots > m_r > 0} \frac{q^{(k_1-1)m_1} \dots q^{(k_r-1)m_r}}{[m_1]_q^{k_1} \dots [m_r]_q^{k_r}},$$

where $[m]_q = \frac{1-q^m}{1-q}$ denotes the usual q -integer. Again, its star version $z_n^*(\mathbf{k}; q)$ is defined by allowing equalities among the m_j . In [1] it was observed that these sums relate to finite and symmetric multiple zeta values when evaluated at a primitive n -th root of unity $q = \zeta_n$, which gives elements in the cyclotomic field $\mathbb{Q}(\zeta_n)$. The connection to finite and symmetric multiple zeta values are then given by the following two theorems.

Theorem 1 [1, Theorem 1.1] *For any index $\mathbf{k} \in (\mathbb{Z}_{\geq 1})^r$, we have*

$$(z_p(\mathbf{k}; \zeta_p) \pmod{\mathfrak{p}_p})_p = \zeta_{\mathcal{A}}(\mathbf{k}), \quad (z_p^*(\mathbf{k}; \zeta_p) \pmod{\mathfrak{p}_p})_p = \zeta_{\mathcal{A}}^*(\mathbf{k}),$$

where $\mathfrak{p}_p = (1 - \zeta_p)$ is the prime ideal of $\mathbb{Z}[\zeta_p]$ generated by $1 - \zeta_p$.

Theorem 2 [1, Theorem 1.2] *For any index $\mathbf{k} \in (\mathbb{Z}_{\geq 1})^r$, the limits*

$$\xi(\mathbf{k}) = \lim_{n \rightarrow \infty} z_n(\mathbf{k}; e^{2\pi i/n}), \quad \xi^*(\mathbf{k}) = \lim_{n \rightarrow \infty} z_n^*(\mathbf{k}; e^{2\pi i/n})$$

exist in \mathbb{C} and it holds that

$$\operatorname{Re} \xi(\mathbf{k}) \equiv \zeta_{\mathcal{S}}(\mathbf{k}), \quad \operatorname{Re} \xi^*(\mathbf{k}) \equiv \zeta_{\mathcal{S}}^*(\mathbf{k})$$

modulo $\zeta(2)\mathcal{Z}$.

Relations among the z_n (resp. z_n^*) therefore give relations among $\zeta_{\mathcal{A}}$ (resp. $\zeta_{\mathcal{A}}^*$) and $\zeta_{\mathcal{S}}$ (resp. $\zeta_{\mathcal{S}}^*$) of the same shape. This gives evidence towards the Conjecture of Kaneko and Zagier above. For example, one can show that we have for all $n \in \mathbb{Z}_{\geq 1}$

$$2z_n^*(4, 1; \zeta_n) + z_n^*(3, 2; \zeta_n) = \frac{(n^4 - 1)(n + 5)}{1440} (1 - \zeta_n)^5 + \frac{n + 2}{3} (1 - \zeta_n)^2 z_n^*(2, 1; \zeta_n),$$

which by the above Theorems implies the relations

$$2\zeta_{\mathcal{A}}^*(4, 1) + \zeta_{\mathcal{A}}^*(3, 2) = 0 \quad \text{and} \quad 2\zeta_{\mathcal{S}}^*(4, 1) + \zeta_{\mathcal{S}}^*(3, 2) \equiv 0 \pmod{\zeta(2)\mathcal{Z}}.$$

It is therefore of great interest to study the relations among the finite multiple harmonic q -series at primitive roots of unity. One such family is given by the following theorem.

Theorem 3 [1, Theorem 1.3] *For any index $\mathbf{k} \in (\mathbb{Z}_{\geq 1})^r$ and any n -th primitive root of unity ζ_n , we have*

$$z_n^*(\mathbf{k}; \zeta_n) = (-1)^{\operatorname{wt}(\mathbf{k})+1} z_n^*(\overline{\mathbf{k}^\vee}; \zeta_n),$$

where $\overline{\mathbf{k}^\vee}$ is the reverse of the Hoffman dual \mathbf{k}^\vee (see [1, Section 2.4]).

This Theorem together with the results above gives a new proof of the duality formulas for $\zeta_{\mathcal{A}}^*(\mathbf{k})$ and $\zeta_{\mathcal{S}}^*(\mathbf{k})$, previously obtained by Hoffman and Jarossay respectively.
